

**System and Method for Concurrent WLAN and WPAN
Wireless Modes From a Single Device**

BACKGROUND OF THE INVENTION

1. Technical Field

5 The present invention relates in general to a system and method for communicating concurrently in a plurality of wireless environments using a single device. More particularly, the present invention relates to a system and method for using a single Wi-Fi device to concurrently
10 communicate in a wireless LAN environment and a wireless PAN environment.

2. Description of the Related Art

 Wi-Fi technology is rapidly being adapted for use in wireless local area networks (WLAN's). A wireless LAN is
15 one in which a mobile user connects to a local area network (LAN) through a wireless connection. Wi-Fi technology is gaining acceptance in consumer and commercial markets as an alternative to a wired LAN due to its excellent interoperability and commodity pricing. Wi-Fi is specified
20 in the Institute of Electrical and Electronics Engineers (IEEE) 802.11 specification (including additions and changes specified in 802.11a, 802.11b, etc). Wi-Fi specifies an Ethernet-like protocol which uses CSMA/CA (carrier sense multiple access with collision avoidance)
25 for channel sharing. Wi-Fi technology currently operates in the 2.4 GHz ISM frequency band or the 5 GHz U-NII frequency band and offers data rates up to 54 Mbps.

Another standard, Bluetooth, revolves around a wireless personal area network (WPAN). Bluetooth is the most common WPAN technology and was used as the basis for the IEEE 802.15.1 standard. A wireless personal area network (WPAN) is used to wirelessly interconnect devices centered on an individual person through a point-to-point or peer-to-peer connection. Typically, a wireless personal area network uses technology that permits communication within a very short range, such as ten meters. A WPAN may serve to interconnect ordinary computing and communicating devices that many people carry with them today. A challenge found, however, is that many peripheral devices, such as printers and handheld devices, are required to support both WLAN interoperability for infrastructure network communication as well as WPAN interoperability for point-to-point communication.

Wi-Fi technology could replace Bluetooth technology as a technology to support WPAN environments, all the while providing lower system cost, higher bandwidth, and better interoperability. A challenge found, however, is that existing Wi-Fi technology does not allow a single device to simultaneously or concurrently support both infrastructure and peer-to-peer environments. In order to support simultaneous infrastructure and peer-to-peer environments using Wi-Fi technology, two Wi-Fi devices are required, one for each environment, thereby increasing a computer system's equipment cost.

What is needed, therefore, is a system and method to support concurrent infrastructure and peer-to-peer environments using a single Wi-Fi device.

SUMMARY

It has been discovered that the aforementioned challenges are resolved by using a Wi-Fi device's infrastructure mode to communicate in a WLAN environment and, during idle WLAN intervals, using the Wi-Fi device's
5 ad hoc mode to communicate in a WPAN environment.

A user wishes to concurrently communicate over a WLAN network and a WPAN network. For example, the user's client may display a presentation by interfacing to a projector
10 over a WPAN, and request access to the Internet over a WLAN. The user's client uses a Wi-Fi device to communicate over wireless networks whereby the Wi-Fi device includes an infrastructure register and an ad hoc register. The infrastructure register stores an infrastructure
15 configuration profile that includes information regarding an infrastructure network (i.e. WLAN), such as a channel number and an IP address. The ad hoc register stores an ad hoc configuration profile that includes information regarding an ad hoc network (i.e. WPAN), such as a channel
20 number and a network name.

The client's Wi-Fi device uses a watchdog timer to switch between infrastructure mode and ad hoc mode. When the client's Wi-Fi device switches to infrastructure mode, the client's Wi-Fi device loads and uses information
25 included in the infrastructure register. Likewise, when the client switches to ad hoc mode, the client's Wi-Fi device loads and uses information included in the ad hoc register.

In addition, the client includes an infrastructure driver, an adhoc driver, and a "code shim". When the client's Wi-Fi device is in infrastructure mode, the client uses the infrastructure driver to send and receive
5 information to an access point over an infrastructure network (i.e. WLAN). When the client's Wi-Fi device is in adhoc mode, the client uses the adhoc driver to send/receive information to/from a peer-to-peer device, such as a projector or a printer, over the adhoc network
10 (i.e. WPAN).

During times when the client's Wi-Fi device is in infrastructure mode, the adhoc driver is inactive and the code shim acts as a virtual adhoc device driver to the client's operating system. Likewise, when the client's Wi-
15 Fi device is in adhoc mode, the infrastructure driver is inactive and the code shim acts as a virtual infrastructure device driver to the client's operating system.

The foregoing is a summary and thus contains, by necessity, simplifications, generalizations, and omissions
20 of detail; consequently, those skilled in the art will appreciate that the summary is illustrative only and is not intended to be in any way limiting. Other aspects, inventive features, and advantages of the present invention, as defined solely by the claims, will become
25 apparent in the non-limiting detailed description set forth below.

BRIEF DESCRIPTION OF THE DRAWINGS

The present invention may be better understood, and its numerous objects, features, and advantages made apparent to those skilled in the art by referencing the accompanying drawings. The use of the same reference symbols in different drawings indicates similar or identical items.

Figure 1 is a diagram showing a client using a single Wi-Fi device to concurrently operate in both a Wireless LAN (WLAN) environment and a Wireless Personal Area Network (WPAN) environment;

Figure 2 is a diagram showing a client's software stack that supports both infrastructure mode and adhoc mode;

Figure 3 is a timing diagram showing a client that is switching modes based upon the expiration of a timer;

Figure 4 is a flowchart showing steps taken in a client's wireless device initializing and adding a new network;

Figure 5 is a flowchart showing steps taken in a client's wireless device loading configuration profiles based upon configuration and network modes;

Figure 6 is a flowchart showing steps taken in a client sending data to an access point and a peer-to-peer device;

Figure 8 is a block diagram of an access point that is capable of adapting to the present invention; and

Figure 9 is a block diagram of peer-to-peer device that is capable of adapting to the present invention.

DETAILED DESCRIPTION

The following is intended to provide a detailed description of an example of the invention and should not be taken to be limiting of the invention itself. Rather,
5 any number of variations may fall within the scope of the invention which is defined in the claims following the description.

Figure 1 is a diagram showing a client using a single Wi-Fi device to concurrently operate in both a Wireless LAN (WLAN) environment and a Wireless Personal Area Network (WPAN) environment. Client 100 uses a Wi-Fi device in "infrastructure" mode at intervals when client 100 is communicating in a WLAN environment and client 100 uses the same device in "adhoc" mode at intervals when client 100 is
10 communicating in a WPAN environment.
15

Client 100 includes infrastructure register 110 and adhoc register 130. Infrastructure register 110 stores an infrastructure configuration profile that includes information regarding infrastructure network 170, such as a
20 channel number and an IP address. Adhoc register 130 stores an adhoc configuration profile that includes information regarding adhoc network 190, such as a channel number and a network name.

Client 100's Wi-Fi device uses a watchdog timer to
25 switch between infrastructure mode and adhoc mode. When client 100's Wi-Fi device switches to infrastructure mode, client 100's Wi-Fi device loads and uses information included in infrastructure register 110. Likewise, when client 100 switches to adhoc mode, client 100's Wi-Fi

device loads and uses information included in adhoc register 130.

In addition, client 100 includes infrastructure driver 120, adhoc driver 140, and code shim 150. When client 100's Wi-Fi device is in infrastructure mode, client 100 uses infrastructure driver 120 to send and receive information to access point 160 over infrastructure network 170. Access point 160 is a wireless LAN device that also allows client 100 to access computer network 165, such as the Internet (see **Figure 8** and corresponding text for further details regarding access point properties). When client 100's Wi-Fi device is in adhoc mode, client 100 uses adhoc driver 140 to send and receive information to peer-to-peer device 180 over adhoc network 190. Peer-to-peer device 180 is a wireless PAN device, such as a projector, PDA, or printer (see **Figure 9** and corresponding text for further details regarding peer-to-peer device properties).

During intervals when client 100's Wi-Fi device is in infrastructure mode, adhoc driver 140 is inactive and code shim 150 acts as a virtual adhoc device driver to client 100's operating system. Likewise, when client 100's Wi-Fi device is in adhoc mode, infrastructure driver 120 is inactive and code shim 150 acts as a virtual infrastructure device driver to client 100's operating system (see **Figures 2, 3,** and corresponding text for further details regarding code shim properties).

Figure 2 is a diagram showing a client's software stack that supports both infrastructure mode and adhoc mode. Software stack 200 includes layer 1 210, layer 2 240, and layer 3 280. Layer 1 210 interfaces with a client's

wireless interface hardware using wireless interface 215. Wireless interface includes timer 220, firmware 225, adhoc register 130, and infrastructure register 110. Wireless interface 215 uses timer 220 as a timer to switch between
5 adhoc mode and infrastructure mode (see **Figures 3, 5,** and corresponding text for further details regarding timer use).

A client's wireless device loads and uses adhoc configuration profile information included in adhoc
10 register 130 during adhoc mode. The adhoc configuration profile includes settings, such as a channel number and a network name, that the client's wireless device uses to communicate with a peer-to-peer device over an adhoc (i.e. WPAN) network. A client's wireless device loads and uses
15 infrastructure configuration profile information included in infrastructure register 110 while it is in infrastructure mode. The infrastructure configuration profile includes settings, such as a channel number and an IP address, that the client's wireless device uses to
20 communicate with a peer-to-peer device over an infrastructure (i.e. WLAN) network. Adhoc register 130 and infrastructure register 110 are the same as that shown in **Figure 1.** Firmware 225 includes standard firmware to operate the client's wireless hardware.

25 Layer 2 240 includes adhoc driver 140, infrastructure driver 120, and code shim 150, which are the same as that shown in **Figure 1.** The client's operating system uses adhoc driver 140 to transfer data to/from a peer-to-peer device over an adhoc network. Likewise, the client's
30 operating system uses infrastructure driver 120 to transfer data to/from an access point over an infrastructure

network. Code shim 150 acts as a virtual device driver for either adhoc driver 140 or infrastructure driver 120 when either of them is inactive. For example, when a client's wireless device is in infrastructure mode, adhoc driver 140
5 is inactive and code shim 150 acts as a virtual adhoc device driver to the client's operating system (see Figure 3 and corresponding text for further details regarding driver availability).

Layer 3 280 includes application client manager 290
10 which is an interface that is used to set up the wireless client for connecting to a WLAN and/or a WPAN device.

Figure 3 is a timing diagram showing a client that is switching modes based upon the expiration of a timer. Timeline 300 shows a watchdog timer running, expiring, and
15 resetting. Adhoc driver status line 320 shows an adhoc driver's status at particular time intervals. Infrastructure driver status line 340 shows an infrastructure driver's status at particular time intervals. Finally, code shim status line 360 shows the
20 status of code shim software acting as a virtual device driver.

At time T1, adhoc driver status line 320 shows that the adhoc driver is ready to send/receive data to/from a peer-to-peer device. Also at time T1, infrastructure
25 driver status line 340 shows that the infrastructure driver is inactive, or offline. In turn, at time T1, code shim status line 360 shows that the code shim is functioning as an infrastructure virtual device driver to a client's operating system during time T1 in order to maintain a
30 network connection.

At time T2, the watchdog timer expires and resets. At time T3, the adhoc driver becomes inactive (i.e. offline), and the infrastructure driver becomes ready. In turn, code shim status line 360 shows, at time T3, that the code shim
5 code switches from being an infrastructure virtual device driver to becoming an adhoc virtual device driver.

At time T4, the timer expires and resets once again. At time T5, the infrastructure driver becomes inactive (i.e. offline), and the adhoc driver becomes ready once
10 again. In turn, code shim status line 360 shows, at time T5, that the code shim code switches from being an adhoc virtual device driver to becoming an infrastructure virtual device driver.

Figure 4 is a flowchart showing steps taken in a client's wireless device initializing and adding a new
15 network. Processing commences at 400, whereupon processing initializes at step 405. A determination is made as to whether to add a new network profile (decision 410). For example, a user may travel to a new worksite and wish to
20 use a particular overhead projector that communicates on a WPAN. In this example, the user adds an adhoc network that corresponds to the overhead projector's WPAN.

If a new network profile does not need to be added, decision 410 branches to "No" branch 418 bypassing network
25 addition steps, and processing ends at 490. On the other hand, if a user wishes to add a new network, decision 410 branches to "Yes" branch 412 whereupon a determination is made as to which type of network to add (decision 420). If the user wishes to add an infrastructure network, decision
30 420 branches to "Infrastructure" branch 422 whereupon

processing receives information from user 435 and creates an infrastructure configuration profile at step 430. For example, the user may provide a network name that corresponds to a new infrastructure network. Once
5 configured, the new infrastructure configuration profile is stored in profile store 450 at step 440. Profile store 450 may be stored on a nonvolatile storage area, such as a nonvolatile memory.

On the other hand, if the user wishes to add an adhoc
10 network, decision 420 branches to "Adhoc" branch 428 whereupon processing receives information from user 435 and creates an adhoc configuration profile at step 460. For example, the user may provide a network name that corresponds to a new adhoc network. Once configured, the
15 new adhoc configuration profile is stored in profile store 450 at step 470.

Once processing stores either an infrastructure configuration profile or an adhoc configuration profile, processing sets a configuration profile mode at step 480.
20 The configuration profile mode informs the client's wireless device as to whether the client should operate in adhoc mode, in infrastructure mode, or both modes. Processing ends at 490.

Figure 5 is a flowchart showing steps taken in a
25 client's wireless device loading configuration profiles based upon configuration and network modes. Processing commences at 500, whereupon a determination is made as to whether to operate in a single configuration mode or a dual configuration mode based on whether both WLAN and WPAN
30 network connections are required by the client (decision

510). This is dynamically decided based upon applications that are being run by a user, such as printing to a WPAN-based printer while connected to an infrastructure WLAN.

5 If the client's wireless device should operate in single configuration mode, decision 510 branches to "Single" branch 512 whereupon processing checks a configuration bit at step 520. The configuration bit identifies whether the client should operate in infrastructure mode or adhoc mode. A determination is made
10 as to whether the client should operate in infrastructure mode or adhoc mode (decision 530).

If the client's wireless device should operate in infrastructure mode, decision 530 branches to "Infrastructure" branch 532 whereupon processing retrieves
15 an infrastructure configuration profile from profile store 450, and loads the profile in infrastructure register 110 (step 535). Infrastructure register 110 and profile store 450 and are the same as that shown in **Figures 1** and **4**, respectively.

20 On the other hand, if the client should operate in adhoc mode, decision 530 branches to "Adhoc" branch 534 whereupon processing retrieves an adhoc configuration profile from profile store 450, and loads the profile in adhoc register 130 (step 540). Adhoc register 130 is the
25 same as that shown in **Figure 1**. Processing ends at 545.

If the client's wireless device should operate in dual configuration mode, decision 510 branches to "Dual" branch 518 whereupon processing retrieves an adhoc configuration profile from profile store 450, and loads the profile in
30 adhoc register 130 (step 550). At step 555, processing

retrieves an infrastructure configuration profile from profile store 450, and loads the profile in infrastructure register 110. Processing sets a watchdog timer at step 560 which informs the client's wireless device when to switch
5 between adhoc mode and infrastructure mode.

Processing starts in adhoc configuration profile mode at step 565. As one skilled in the art can appreciate, a client's wireless device may start in infrastructure configuration profile mode. Processing stays in adhoc mode
10 until the watchdog timer expires (step 570), at which point processing switches to infrastructure configuration profile mode at step 575. Processing resets the timer at step 578, and waits for the timer to expire at step 580, all the while in infrastructure mode.

15 Once the watchdog timer expires, a determination is made as to whether to continue processing (decision 590). If processing should continue, decision 590 branches to "Yes" branch 592 which loops back to switch profiles. This looping continues until processing should stop, at which
20 point decision 590 branches to "No" branch 598 whereupon processing ends at 599.

Figure 6 is a flowchart showing steps taken in a client sending data to an access point and a peer-to-peer device. Processing commences at 600, whereupon processing
25 polls adhoc device driver 140 and infrastructure device driver 120. Adhoc device driver 140 and infrastructure device driver 120 are the same as that shown in **Figure 1**. A determination is made as to which device is in a ready state (decision 610).

If infrastructure device driver 120 is in the ready state, decision 610 branches to "Infrastructure" branch 612 whereupon a determination is made as to whether a request is pending to send or receive data to an access point (decision 615). If a request is pending, decision 615 branches to "Yes" branch 617 whereupon processing uses infrastructure device driver 120 to transfer data to/from access point 160 (step 620). Access point 160 is the same as that shown in **Figure 1**. On the other hand, if a request is not pending, decision 615 branches to "No" branch 619 bypassing data transfer steps.

A determination is made as to whether a watchdog timer has expired (decision 635) (see **Figure 3** and corresponding text for further details watchdog timer expiration). If the watchdog timer has not yet expired, decision 635 branches to "No" branch 637 which loops back to process more requests. This looping continues until the watchdog timer expires, at which point decision 635 branches to "Yes" branch 639, whereupon processing sets the infrastructure configuration mode busy (e.g. infrastructure driver 120) at step 640.

If adhoc device driver 140 is in the ready state, decision 610 branches to "Adhoc" branch 614 whereupon a determination is made as to whether a request is pending to send and/or receive data from a peer-to-peer device (decision 645). If a request is pending, decision 645 branches to "Yes" branch 647 whereupon processing uses adhoc device driver 140 to transfer data to/from peer-to-peer device 180 (step 650). Peer-to-peer device 180 is the same as that shown in **Figure 1**. On the other hand, if a

request is not pending, decision 645 branches to "No" branch 649 bypassing data transfer steps.

A determination is made as to whether the watchdog timer has expired (decision 655). If the watchdog timer has not expired, decision 655 branches to "No" branch 657 which loops back to process more requests. This looping continues until the timer expires, at which point decision 655 branches to "Yes" branch 659, whereupon processing sets the adhoc configuration mode busy (e.g. adhoc register 140) at step 660.

A determination is made as to whether to continue processing (decision 670). If processing should continue, decision 670 branches to "Yes" branch 672 which loops back to process more requests. This looping continues until processing should stop, at which point decision 670 branches to "No" branch 674 whereupon processing ends at 680.

Figure 7 is a block diagram of an information handling system, such as a client device, capable of implementing the present invention. Figure 7 illustrates client 100 which is a simplified example of a client capable of performing the computing operations described herein. Client 100 includes wireless interface 710 that includes transceiver 715. Transceiver 715 is an RF (radio frequency) transmitter that uses antenna 755 to communicate with other devices on infrastructure network 170 and adhoc network 190. Client 100, infrastructure network 170 and adhoc network 190 are the same as that shown in Figure 1.

TX FIFO 720 and RX FIFO 725 couple controller 730 to transceiver 715 and are used to buffer transmission and

reception of data packets that are sent to and received from network devices. Controller 730 includes mode bit 735, timer 740, adhoc register 130, and infrastructure register 110. Client 100 checks mode bit 735 to determine
5 whether to be in single network mode or dual network mode. Timer 740 is used to identify times at which to switch between modes. Adhoc register 130 includes information pertaining to an adhoc configuration profile. And, infrastructure register 110 includes information pertaining
10 to an infrastructure configuration profile.

PCI bus controller 760 operationally couples a variety of modules within client 100. A standard processing subsection is coupled to PCI bus controller 760 and consists of microprocessor 770, memory controller 765, and
15 memory 772. PCI bus controller 760 is also coupled to keyboard/mouse 775 in which a user uses to input information, such as a network name. PCI bus controller 760 is also coupled to DASD 780 that includes hard drive 785 and optical device 786. Client 100 also includes video
20 controller 790 which displays data on display 795 for a user to view.

While the computer system described in **Figure 7** is capable of executing the processes described herein, this computer system is simply one example of a computer system.
25 Those skilled in the art will appreciate that many other computer system designs are capable of performing the processes described herein.

Figure 8 is a block diagram of an access point that is capable of adapting to the present invention. Access point

160 includes three modules which are wireless interface 870, baseband processing 840, and LAN interface 805.

Wireless LAN interface 870 may be any wireless interface using a wireless medium such as RF, infrared, 5 VHF, UHF, or microwave. In one embodiment, wireless interface 870 is implemented as an 802.11 compliant wireless local area network interface. LAN interface 805 may be a wired land-based network interface, an optical network interface, such as a fiber-optic network interface, 10 or a second wireless network interface. In one embodiment, LAN interface 805 is implemented as an interface for an Ethernet land-based network. LAN interface 805 typically connects to or bridges to a backbone network that provides resources and services, such as computer network 802. 15 Wireless LAN interface 870 provides resources and services found on a backbone network to wireless clients that are associated to wireless LAN interface 870.

Baseband processing (or flow controller) 840 bridges and controls the flow of traffic between wireless clients 20 coupled through wireless LAN interface 870 and the backbone network coupled to LAN interface 805. Baseband processing 840 maintains a FIFO buffer for bidirectional traffic between interfaces 870 and 805. Baseband processing 840 may be implemented entirely in hardware, or partially in 25 hardware and partially in software/firmware. In the embodiment shown in **Figure 8**, baseband processing 840 is implemented using microprocessor 850 having program storage 855 that stores boot code and microcode for execution on a microprocessor 850. The boot code is typically executed 30 directly from program storage 855 while the microcode is typically transferred to memory 260 for faster execution.

Baseband processing 840 also includes interface controller 845 that performs lower-level functions, such as handshaking functions, that are required to interface wireless interface 870 to LAN interface 805.

5 The construction of wireless interface 870 includes physical layer RF transceiver 890, transmit and receive FIFO's 880 and 885, respectively, and controller 875 for interfacing to baseband processing 840. Wireless LAN interface 870 includes antenna 895 for coupling
10 electromagnetic energy to the atmosphere, such as infrastructure network 170.

 The construction of LAN interface 805 includes Ethernet physical layer 815, transmit and receive FIFO's 820 and 825 and controller 830 for interfacing to baseband
15 processing 840. Ethernet physical layer 815 couples to backbone network 802. Controller's 830 and 875 may be implemented in hardware, or as a combination of hardware and software/firmware components. In this embodiment, however, controllers 830 and 875 are implemented in
20 hardware for faster operation.

Figure 9 is a block diagram of peer-to-peer device that is capable of adapting to the present invention. Peer-to-peer device 180 includes wireless interface 910 that includes transceiver 915. Transceiver 915 is an RF
25 (radio frequency) transmitter that uses antenna 940 to communicate with other devices on adhoc network 160. Peer to peer device 180 and adhoc network 160 are the same as that shown in **Figure 1**.

 TX FIFO 920 and RX FIFO 925 couple controller 930 to
30 transceiver 915 and are used to buffer transmission and

reception of data packets that are sent to and received from network devices. Controller 730 is coupled to I/O controller 950 which manages data flow between input and output devices. I/O controller 950 couples to memory 955 and memory controller 960 which manages memory storage and retrieval with the assistance of processor 970 and memory 965. I/O controller 950 also couples to nonvolatile storage 975 and touch pad controller 980 which receives information from touch pad display 990.

One of the preferred implementations of the invention is an application, namely, a set of instructions (program code) in a code module which may, for example, be resident in the random access memory of the computer. Until required by the computer, the set of instructions may be stored in another computer memory, for example, on a hard disk drive, or in removable storage such as an optical disk (for eventual use in a CD ROM) or floppy disk (for eventual use in a floppy disk drive), or downloaded via the Internet or other computer network. Thus, the present invention may be implemented as a computer program product for use in a computer. In addition, although the various methods described are conveniently implemented in a general purpose computer selectively activated or reconfigured by software, one of ordinary skill in the art would also recognize that such methods may be carried out in hardware, in firmware, or in more specialized apparatus constructed to perform the required method steps.

While particular embodiments of the present invention have been shown and described, it will be obvious to those skilled in the art that, based upon the teachings herein, changes and modifications may be made without departing

from this invention and its broader aspects and, therefore, the appended claims are to encompass within their scope all such changes and modifications as are within the true spirit and scope of this invention. Furthermore, it is to
5 be understood that the invention is solely defined by the appended claims. It will be understood by those with skill in the art that if a specific number of an introduced claim element is intended, such intent will be explicitly recited in the claim, and in the absence of such recitation no such
10 limitation is present. For a non-limiting example, as an aid to understanding, the following appended claims contain usage of the introductory phrases "at least one" and "one or more" to introduce claim elements. However, the use of such phrases should not be construed to imply that the
15 introduction of a claim element by the indefinite articles "a" or "an" limits any particular claim containing such introduced claim element to inventions containing only one such element, even when the same claim includes the introductory phrases "one or more" or "at least one" and
20 indefinite articles such as "a" or "an"; the same holds true for the use in the claims of definite articles.
